## Abstract

The present invention describes a novel treatment for movement disorders, including tardive dyskinesia, tic disorders, Tourette's syndrome, and blepharospasm, and other focal dystonias. The treatment of the present invention utilizes agents that simultaneously act as NMDA-type glutamate receptor antagonists and GABA-A receptor agonists. Preferably these two activities are characteristic of a single agent, for example acamprosate. Alternatively, separate agents having these activities can be combined and administered together. The invention also provides a third agent that acts as a non-competitive NMDA-receptor blocking agent or ion channel blocker that augments the effect of the primary treatment. A particularly preferred ion channel blocking agent is magnesium. Alternatively, magnesium can be administered alone for prevention and treatment of movement disorders.
